Diastolic Relaxation Of The Heart

Diastolic dysfunction is a cardiac condition caused by a “stiffening” of the

Relaxation Of The
heart's ventricles (the
major pumping
chambers). This relative
stiffness restricts the
heart's ability to fill up
with blood in between
heart beats.

**An Overview of
Diastolic
Dysfunction and
Heart Failure**

Diastolic heart failure,
in which the left
ventricle stiffens and
bulks up, is different
from systolic heart

failure, in which the left ventricle becomes weak and flabby.

Ejection fraction, a key measure of the heart's pumping ability, is normal in diastolic heart failure and low in systolic heart failure.

Diastolic heart failure - Harvard Health

The primary method of diagnosing diastolic dysfunction, a type of heart failure in which

the heart isn't able to relax fully after each beat, is with an echocardiogram (ECG) and, sometimes, other imaging tests. Leading up to such a test the condition may be suspected based on symptoms shared by other types of heart failure.

How Diastolic Dysfunction is Diagnosed

Congestive heart

failure affects millions of people around the world. It is usually associated with heart disease brought about by increasing age, obesity, high blood pressure, irregularities in heart rate and rhythm and lack of oxygenation in the heart (ischemia). Physiologically it may be brought about by an abnormal left ventricular diastolic relaxation which is the
